1 Cartesian Coordinates and Generalized Coordinates

The set of coordinates used to describe the motion of a dynamic system is not unique. For example, consider an elastic pendulum (a mass on the end of a spring). The position of the mass at any point in time may be expressed in Cartesian coordinates \((x(t), y(t))\) or in terms of the angle of the pendulum and the stretch of the spring \((\theta(t), u(t))\). Of course, these two coordinate systems are related. For Cartesian coordinates centered at the pivot point,

\[
x(t) = (l + u(t)) \sin \theta(t) \\
y(t) = -(l + u(t)) \cos \theta(t)
\]

where \(l\) is the un-stretched length of the spring. Let’s define

\[
\begin{bmatrix}
  r_1(t) \\
n(t)
\end{bmatrix} = \begin{bmatrix}
x(\theta(t), u(t)) \\
y(\theta(t), u(t))
\end{bmatrix} = \begin{bmatrix}
(l + u(t)) \sin \theta(t) \\
-(l + u(t)) \cos \theta(t)
\end{bmatrix}
\]

and

\[
q(t) = \begin{bmatrix}
q_1(t) \\
n_2(t)
\end{bmatrix} = \begin{bmatrix}
\theta(t) \\
u(t)
\end{bmatrix}
\]

so that \(r(t)\) is a function of \(q(t)\).

The potential energy, \(V\), may be expressed in terms of \(r\) or in terms of \(q\).

In Cartesian coordinates, the velocities are

\[
\dot{r}(t) = \begin{bmatrix}
\dot{r}_1(t) \\
\dot{n}(t)
\end{bmatrix} = \begin{bmatrix}
\dot{u}(t) \sin \theta(t) + (l + u(t)) \cos \theta(t) \dot{\theta}(t) \\
-\ddot{u}(t) \cos \theta(t) + (l + u(t)) \sin \theta(t) \dot{\theta}(t)
\end{bmatrix}
\]

So, in general, Cartesian velocities \(\dot{r}(t)\) can be a function of both the velocity and position of some other coordinates \((\dot{q}(t)\) and \(q(t)\)). Such coordinates \(q\) are called general coordinates. The kinetic energy, \(T\), may be expressed in terms of either \(\dot{r}\) or, more generally, in terms of \(\dot{q}\) and \(q\).

Small changes (or variations) in the rectangular coordinates, \((\delta x, \delta y)\) consistent with all displacement constraints, can be found from variations in the generalized coordinates \((\delta \theta, \delta u)\).

\[
\delta x = \frac{\partial x}{\partial \theta} \delta \theta + \frac{\partial x}{\partial u} \delta u = (l + u(t)) \cos \theta(t) \delta \theta + \sin \theta(t) \delta u
\]
\[ \delta y = \frac{\partial y}{\partial \theta} \delta \theta + \frac{\partial y}{\partial u} \delta u = (l + u(t)) \sin \theta(t) \delta \theta - \cos \theta(t) \delta u \] (7)

2 Principle of Virtual Displacements

Virtual displacements \( \delta r_i \) are any displacements consistent with the constraints of the system. The principle of virtual displacements\(^1\) says that the work of real external forces through virtual external displacements equals the work of the real internal forces arising from the real external forces through virtual internal displacements consistent with the real external displacements. In system described by \( n \) coordinates \( r_i \), with \( n \) internal inertial forces \( m_i \ddot{r}_i(t) \), potential energy \( V(r) \), and \( n \) external forces \( p_i \) collocated with coordinates \( r_i \), the principle of virtual displacements says,

\[ \sum_{i=1}^{n} \left( m_i \ddot{r}_i + \frac{\partial V}{\partial r_i} \right) \delta r_i = \sum_{i=1}^{n} (p_i(t)) \delta r_i \] (8)

3 Derivation of d’Alembert’s principle from Minimum Total Potential Energy

The total potential energy, \( \Pi \), is defined as the internal potential energy, \( V \), minus the potential energy of external forces\(^2\). In terms of the \( r \) (Cartesian) coordinate system and \( n \) forces \( f_i \) collocated with the \( n \) displacement coordinates, \( r_i \), the total potential energy is given by equation (9).

\[ \Pi(r) = V(r) - \sum_{i=1}^{n} f_i r_i . \] (9)

The principle of minimum total potential energy states that the total potential energy is minimized in a condition of equilibrium. Minimizing the total potential energy is the same as setting the variation of the total potential energy to zero. For any arbitrary set of “variational” displacements \( \delta r_i(t) \), consistent with displacement constraints,

\[ \min_r \Pi(r) \Rightarrow \delta \Pi(r) = 0 \iff \sum_{i=1}^{n} \frac{\partial \Pi}{\partial r_i} \delta r_i = 0 \iff \sum_{i=1}^{n} \frac{\partial V}{\partial r_i} \delta r_i - \sum_{i=1}^{n} f_i \delta r_i = 0 , \] (10)

In a dynamic situation, the forces \( f_i \) can include inertial forces, damping forces, and external loads. For example,

\[ f_i(t) = -m_i \ddot{r}_i(t) + p_i(t) , \] (11)

where \( p_i \) is an external force collocated with the displacement coordinate \( r_i \). Substituting equation (11) into equation (10), and rearranging slightly, results in the d’Alembert equations, the same as equation (8) found from the principle of virtual displacements,

\[ \sum_{i=1}^{n} \left( m_i \ddot{r}_i(t) + \frac{\partial V}{\partial r_i} - p_i(t) \right) \delta r_i = 0 . \] (12)

\(^1\)d’Alembert, J-B le R, 1743

\(^2\)In solid mechanics, internal strain energy is conventionally assigned the variable \( U \), whereas the potential energy of external forces is conventionally assigned the variable \( V \). In Lagrange’s equations potential energy is assigned the variable \( V \) and kinetic energy is denoted by \( T \).
In equations (8) and (12) the virtual displacements (i.e., the variations) \( \delta r_i \) must be arbitrary and independent of one another; these equations must hold for each coordinate \( r_i \) individually.

\[
m_i \ddot{r}_i(t) + \frac{\partial V}{\partial r_i} - p_i(t) = 0 .
\] (13)

### 4 Derivation of Lagrange’s equations from d’Alembert’s principle

For many problems equation (13) is enough to determine equations of motion. However, in coordinate systems where the kinetic energy depends on the position and velocity of some generalized coordinates, \( q(t) \) and \( \dot{q}(t) \), expressions for inertial forces become more complicated.

The first goal, then, is to relate the work of inertial forces (\( \sum_i m_i \ddot{r}_i \delta r_i \)) to the kinetic energy in terms of a set of generalized coordinates. To do this requires a change of coordinates from variations in \( n \) Cartesian coordinates \( \delta r \) to variations in \( m \) generalized coordinates \( \delta q \),

\[
\delta r_i = \sum_{j=1}^{m} \frac{\partial r_i}{\partial q_j} \delta q_j = \sum_{j=1}^{m} \frac{\partial \dot{r}_i}{\partial q_j} \delta q_j \quad \text{and} \quad \frac{d}{dt} \delta r_i = \dot{\delta r}_i = \sum_{j=1}^{m} \frac{\partial r_i}{\partial q_j} \delta q_j .
\] (14)

Now, consider the kinetic energy of a constant mass \( m \). The kinetic energy in terms of velocities in Cartesian coordinates is given by\( T(\dot{r}) = \frac{1}{2}m(\dot{r}_1^2 + \dot{r}_2^2 + \dot{r}_3^2) \), and

\[
\frac{\partial T}{\partial \dot{r}_i} \delta r_i = m_i \ddot{r}_i \delta r_i .
\] (15)

Applying the product and chain rules of calculus to equation (15),

\[
\frac{d}{dt} \left( \frac{\partial T}{\partial \dot{r}_i} \delta r_i \right) = m_i \ddot{r}_i \delta r_i + m_i \dot{r}_i \frac{d}{dt} \delta r_i ,
\] (16)

\[
\frac{d}{dt} \left( \frac{\partial T}{\partial \dot{r}_i} \sum_{j=1}^{m} \frac{\partial \dot{r}_i}{\partial q_j} \delta q_j \right) = m_i \ddot{r}_i \delta r_i + \frac{\partial T}{\partial \dot{r}_i} \dot{\delta r}_i ,
\] (17)

\[
m_i \ddot{r}_i \delta r_i = \frac{d}{dt} \left( \frac{\partial T}{\partial \dot{r}_i} \sum_{j=1}^{m} \frac{\partial \dot{r}_i}{\partial q_j} \delta q_j \right) - \frac{\partial T}{\partial r_i} \sum_{j=1}^{m} \frac{\partial \dot{r}_i}{\partial q_j} \delta q_j .
\] (18)

Equation (18) is a step to getting the work of inertial forces (\( \sum_i m_i \ddot{r}_i \delta r_i \)) in terms of a set of generalized coordinates \( q_j \). Next, changing the derivatives of the potential energy from \( r_i \) to \( q_j \),

\[
\frac{\partial V}{\partial r_i} \delta r_i = \sum_{j=1}^{m} \frac{\partial V}{\partial q_j} \frac{\partial r_i}{\partial q_j} \delta q_j .
\] (19)

Finally, expressing the work of non-conservative forces \( p_i \) in terms of the new coordinates \( q_j \),

\[
\sum_{i=1}^{n} p_i(t) \delta r_i = \sum_{i=1}^{n} p_i(t) \sum_{j=1}^{m} \frac{\partial r_i}{\partial q_j} \delta q_j = \sum_{j=1}^{m} \sum_{i=1}^{n} p_i(t) \frac{\partial r_i}{\partial q_j} \delta q_j = \sum_{j=1}^{m} Q_j(t) \delta q_j ,
\] (20)
where \( Q_j(t) \) are generalized forces, collocated with the generalized coordinates, \( q_j(t) \). Substituting equations (18), (19) and (20) into d’Alembert’s equation (12), rearranging the order of the summations, factoring out the common \( \delta q_j \), canceling the \( \partial r_i \) and \( \partial \dot{r}_i \) terms, and eliminating the sum over \( i \), leaves the equation in terms of \( q_j \) and \( \dot{q}_j \),

\[
\sum_{i=1}^{n} \left[ \frac{d}{dt} \left( \frac{\partial T}{\partial \dot{r}_i} \sum_{j=1}^{m} \frac{\partial \dot{r}_i}{\partial q_j} \delta q_j \right) - \frac{\partial T}{\partial r_i} \sum_{j=1}^{m} \frac{\partial \dot{r}_i}{\partial q_j} \delta q_j + \sum_{j=1}^{m} \frac{\partial V}{\partial q_j} \frac{\partial r_i}{\partial r_j} \delta q_j - p_i(t) \sum_{j=1}^{m} \frac{\partial r_i}{\partial q_j} \delta q_j \right] = 0
\]

\[
\sum_{j=1}^{m} \left[ \frac{d}{dt} \left( \frac{\partial T}{\partial \dot{q}_j} \right) - \frac{\partial T}{\partial q_j} + \frac{\partial V}{\partial q_j} - Q_j \right] \delta q_j = 0
\]

The variations \( \delta q_j \) must be arbitrary and independent of one another; this equation must hold for each generalized coordinate \( q_j \) individually. Removing the summation over \( j \) and canceling out the common \( \delta q_j \) factor results in Lagrange’s equations,

\[
\frac{d}{dt} \left( \frac{\partial T}{\partial \dot{q}_j} \right) - \frac{\partial T}{\partial q_j} + \frac{\partial V}{\partial q_j} - Q_j = 0
\]

are which are applicable in any coordinate system, Cartesian or not.

5 The Lagrangian

Lagrange’s equations may be expressed more compactly in terms of the Lagrangian of the energies,

\[
L(q, \dot{q}, t) \equiv T(q, \dot{q}, t) - V(q, t)
\]

Since the potential energy \( V \) depends only on the positions, \( q \), and not on the velocities, \( \dot{q} \), Lagrange’s equations may be written,

\[
\frac{d}{dt} \left( \frac{\partial L}{\partial \dot{q}_j} \right) - \frac{\partial L}{\partial q_j} - Q_j = 0
\]

\(^3\text{Lagrange, J.L., } \textit{Mecanique analytique}, \text{ Mm Ve Courcier, 1811.}\)
6 Derivation of Hamilton’s principle from d’Alembert’s principle

The variation of the potential energy \( V(\mathbf{r}) \) may be expressed in terms of variations of the coordinates \( r_i \)

\[
\delta V = \sum_{i=1}^{n} \frac{\partial V}{\partial r_i} \delta r_i = \sum_{i=1}^{n} f_i \delta r_i .
\]  

(24)

where \( f_i \) are potential forces collocated with coordinates \( r_i \). In Cartesian coordinates, the variation of the kinetic energy \( T(\dot{\mathbf{r}}) \)

\[
T = \sum_{i=1}^{n} \frac{1}{2} m_i \dot{r}_i^2 
\]  

(25)

may be expressed in terms of variations of the coordinate velocities, \( \dot{r}_i \)

\[
\delta T = \sum_{i=1}^{n} \frac{\partial T}{\partial \dot{r}_i} \delta \dot{r}_i = \sum_{i=1}^{n} m_i \dot{r}_i \delta \dot{r}_i .
\]  

(26)

For a system of \( n \) particle masses \( m_i \) acted on by \( n \) internal forces \( f_i \) of the potential \( V \), d’Alembert’s principle (8 or 12), is

\[
\sum_{i=1}^{n} m_i \ddot{r}_i \delta r_i + \sum_{i=1}^{n} f_i \delta r_i = 0
\]  

(27)

Integrating d’Alembert’s equation over a finite time period,

\[
\int_{t_1}^{t_2} \sum_{i=1}^{n} m_i \ddot{r}_i \delta r_i \, dt + \int_{t_1}^{t_2} \sum_{i=1}^{n} f_i \delta r_i \, dt = 0 \\
\sum_{i=1}^{n} \int_{t_1}^{t_2} m_i \frac{d}{dt} \dot{r}_i \delta r_i \, dt + \int_{t_1}^{t_2} \delta V \, dt = 0 \\
\sum_{i=1}^{n} \left[ m_i \dot{r}_i \delta r_i \bigg|_{t_1}^{t_2} - \int_{t_1}^{t_2} m_i \dot{r}_i \frac{d}{dt} \delta r_i \, dt \right] + \int_{t_1}^{t_2} \delta V \, dt = 0 \\
- \int_{t_1}^{t_2} \sum_{i=1}^{n} m_i \dot{r}_i \delta \dot{r}_i \, dt + \int_{t_1}^{t_2} \delta V \, dt = 0 \\
- \int_{t_1}^{t_2} \delta T \, dt + \int_{t_1}^{t_2} \delta V \, dt = 0 \\
\delta \int_{t_1}^{t_2} (T - V) \, dt = 0
\]  

(28)

In this derivation we consider a variation of the coordinate motions \( \delta r(t) \) from \( t_1 \) to \( t_2 \). That is, \( \delta r(t_1) = 0 \) and \( \delta r(t_2) = 0 \), which eliminates the first term in the third line. The fourth line involves a transposition of the variation and the derivative \( (d(\delta r)/dt = \delta \dot{r}) \). The last line is a statement of Hamilton’s principle, which is presented formally in the next section. Note that kinetic energy and potential energy are scalar valued quantities, invariant to changes in coordinate systems. So, while Hamilton’s principle is derived here in the context of Cartesian coordinates, it applies to generalized coordinates, as well.
Define a Lagrangian of kinetic and potential energies

\[ L(q, \dot{q}, t) = T(q, \dot{q}, t) - V(q, t) \]  

(29)

and define an action potential functional

\[ S[q(t)] = \int_{t_1}^{t_2} L(q, \dot{q}, t) \, dt \]  

(30)

with end points \( q_1 = q(t_1) \) and \( q_2 = q(t_2) \). Consider the true path of \( q(t) \) from \( t_1 \) to \( t_2 \) and a variation of the path, \( \delta q(t) \) such that \( \delta q(t_1) = 0 \) and \( \delta q(t_2) = 0 \).

**Hamilton’s principle:**

The solution \( q(t) \) is an extremum of the action potential \( S[q(t)] \)

\[ \iff \delta S[q(t)] = 0 \]

\[ \iff \int_{t_1}^{t_2} \delta L(q, \dot{q}, t) \, dt = 0 \]

Substituting the Lagrangian into Hamilton’s principle,

\[ \int_{t_1}^{t_2} \left\{ \sum_i \left[ \frac{\partial T}{\partial \dot{q}_i} \delta \dot{q}_i + \frac{\partial T}{\partial q_i} \delta q_i - \frac{\partial V}{\partial q_i} \delta q_i \right] \right\} \, dt = 0 \]

We wish to factor out the independent variations \( \delta q_i \), however the first term contains the variation of the derivative, \( \delta \dot{q}_i \). If the conditions for admissible variations in position \( \delta q \) fully specify the conditions for admissible variations in velocity \( \delta \dot{q} \), the variation and the differentiation can be transposed,

\[ \frac{d}{dt}\delta q_i = \delta \dot{q}_i \]  

(31)

and we can integrate the first term by parts,

\[ \int_{t_1}^{t_2} \frac{\partial T}{\partial \dot{q}_i} \delta \dot{q}_i = \frac{\partial T}{\partial \dot{q}_i} \delta q_i \bigg|_{t_1}^{t_2} - \int_{t_1}^{t_2} \frac{d}{dt} \left( \frac{\partial T}{\partial \dot{q}_i} \right) \delta q_i \, dt \]

Since \( \delta q(t_1) = 0 \) and \( \delta q(t_2) = 0 \),

\[ \int_{t_1}^{t_2} \left\{ \sum_i \left[ - \frac{d}{dt} \left( \frac{\partial T}{\partial \dot{q}_i} \right) \delta q_i + \frac{\partial T}{\partial q_i} \delta q_i - \frac{\partial V}{\partial q_i} \delta q_i \right] \right\} \, dt = 0 \]

The variations \( \delta q_i \) must be arbitrary, so the term within the square brackets must be zero for all \( i \).

\[ \frac{d}{dt} \left( \frac{\partial T}{\partial \dot{q}_i} \right) - \frac{\partial T}{\partial q_i} + \frac{\partial V}{\partial q_i} = 0. \]

---

\[ \sum (f_i - m_i a_i) \delta r_i = 0 \]

\[ \frac{d}{dt} \frac{\partial L}{\partial \dot{q}_i} - \frac{\partial L}{\partial q_i} = Q_i \]

\[ G = \frac{1}{2} (\ddot{q} - a)^T M (\ddot{q} - a) \]

\[ \delta G = 0 \]

\[ S = \int_{t_1}^{t_2} L(q, \dot{q}, t) dt \]

\[ \delta S = 0 \]
9 Example: an elastic pendulum

For an elastic pendulum (a mass swinging on the end of a spring), it is much easier to express the kinetic energy and the potential energy in terms of $\theta$ and $u$ than $x$ and $y$.

$$
T(\theta, u, \dot{\theta}, \dot{u}) = \frac{1}{2} M((l + u)\dot{\theta})^2 + \frac{1}{2} M\dot{u}^2 \tag{32}
$$

$$
V(\theta, u) = Mg(l - (l + u) \cos \theta) + \frac{1}{2} Ku^2 \tag{33}
$$

Lagrange’s equations require the following derivatives (where $q_1 = \theta$ and $q_2 = u$):

$$
d\frac{\partial T}{\partial \dot{q}_1} = \frac{d\partial T}{dt} = \frac{d}{dt}(M(l + u)^2 \dot{\theta}) = M(2(l + u) \dot{u} \dot{\theta} + (l + u)^2 \ddot{\theta}) \tag{34}
$$

$$
\frac{\partial T}{\partial \dot{q}_1} = \frac{\partial T}{\partial \dot{\theta}} = 0 \tag{35}
$$

$$
\frac{\partial V}{\partial q_1} = \frac{\partial V}{\partial \theta} = Mg(l + u) \sin \theta \tag{36}
$$

$$
\frac{d\partial T}{dt} = \frac{d\partial T}{dt} = M \dot{u} = M \ddot{u} \tag{37}
$$

$$
\frac{\partial T}{\partial q_2} = \frac{\partial T}{\partial u} = M(l + u) \dot{\theta}^2 \tag{38}
$$

$$
\frac{\partial V}{\partial q_2} = \frac{\partial V}{\partial u} = Ku - Mg \cos \theta \tag{39}
$$

Substituting these derivatives into Lagrange’s equations for $q_1$ gives

$$
M(2(l + u) \ddot{u} \theta + (l + u)^2 \dddot{\theta}) + Mg(l + u) \sin \theta = 0 \tag{40}
$$

Substituting these derivatives into Lagrange’s equations for $q_2$ gives

$$
M \ddot{u} - M(l + u) \dot{\theta}^2 + Ku - Mg \cos \theta = 0 \tag{41}
$$

These last two equations represent a pair of coupled nonlinear ordinary differential equations describing the unconstrained motion of an elastic pendulum. Equation (40) represents moments (N.m) colocated with $\theta$. Equation (41) represents forces (N) colocated with $u$. They may be written in matrix form as

$$
\begin{bmatrix}
M(l + u)^2 & 0 \\
0 & M
\end{bmatrix}
\begin{bmatrix}
\ddot{\theta} \\
\ddot{u}
\end{bmatrix}
= \begin{bmatrix}
-Mg(l + u) \sin \theta - 2M(l + u) \dot{\theta} \\
M(l + u) \dot{\theta}^2 - Ku + Mg \cos \theta
\end{bmatrix} \tag{42}
$$

or

$$
M(q(t), t) \ddot{q}(t) = Q(q(t), \dot{q}(t), t) \tag{43}
$$

As can be seen, the inertial terms (involving mass) are more complicated than just $M\ddot{r}$, and can involve position, velocity, and acceleration of the generalized coordinates. By carefully relating forces in Cartesian coordinates to those in generalized coordinates through free-body diagrams the same equations of motion may be derived, but doing so with Lagrange’s equations is often more straight-forward once the kinetic and potential energies are derived.
10 Maple and Mathematica software to compute derivatives for Lagrange's equations

10.1 A forced spring-mass-damper oscillator

Consider a forced mass-spring-damper oscillator . . . basically the same as the elastic pendulum with just the \( u(t) \) coordinate, (without the \( \theta \) coordinate), but with some linear viscous damping in parallel with the spring, and external forcing \( f(t) \), collocated with the displacement \( u(t) \).

\[
T(u, \dot{u}) = \frac{1}{2} M \dot{u}(t)^2 \\
V(u) = \frac{1}{2} K u(t)^2 \\
p(u, \dot{u}) \delta u = -c \dot{u}(t) \delta u + f(t) \delta u
\]

where \( (p \, \delta u) \) is the work of real non-conservative forces through a virtual displacement \( \delta u \), in which the damping force is \( c \dot{u} \) and the external driving force is \( f(t) \).

10.1.1 Using Maple

The Maple software may be used to apply Lagrange's equations to these expressions for kinetic energy, \( T \), potential energy \( V \), and the work of non-conservative forces and external forcing, \( W \). Here are the Maple commands:

\[
> \text{with(Physics):} \\
> \text{Setup(mathematicalnotation=true)} \\
> v := \text{diff}(u(t),t); \\
> T := \frac{1}{2} M (\text{diff}(u(t),t))^2; \\
> V := \frac{1}{2} K u(t)^2; \\
> p := -C \text{diff}(u(t),t) + f(t); \\
\]

The lines above setup Maple to invoke the desired functional notation, define the velocities \( v \) as the derivatives of time-dependent displacements \( u(t) \), and represent the kinetic
energy $T$, potential energy $V$, and the external and non-conservative forces $p$. The subsequent lines evaluate the derivatives and combine the derivatives into Lagrange’s equations to give us the equations of motion.

\[
\begin{align*}
\frac{d}{dt} \frac{dT}{dv} &= \frac{d}{dt} \left( M \frac{du(t)}{dt} \right) \\
\frac{d}{dt} \frac{ddt\_dTdv}{dt} &= \frac{d}{dt} \left( \frac{1}{2} M \frac{du(t)}{dt} \right) \\
\frac{dTdu}{dt} &= 0 \\
\frac{dVdu}{dt} &= K u(t) \\
Q &= p \frac{du(t)}{dt} \\
EOM &= \frac{ddt\_dTdv}{dt} - \frac{dTdu}{dt} + \frac{dVdu}{dt} = Q
\end{align*}
\]

> quit

...giving us the expected equation of motion (EOM) ...

\[M\ddot{u}(t) + C\dot{u}(t) + Ku(t) = f(t)\]
10.1.2 Using Mathematica

The same problem using Mathematica software is solved as follows:

\[ v[t] = D[u[t], t] \]
\[ u'[t] \]
\[ T[t] = 1 / 2 * M * v[t]^2 \]
\[ (1/2) M u'[t] 2 \]
\[ V[t] = 1 / 2 * K * u[t]^2 \]
\[ (1/2) K u[t] 2 \]
\[ Q[t] = -C D[u[t], t] + f[t] \]
\[ f[t] - C u'[t] \]
\[ dTdv[t] = D[T[t], v[t]] \]
\[ M u'[t] \]
\[ ddTdvdt[t] = D[ddTdv[t], t] \]
\[ M u''[t] \]
\[ dVdu[t] = D[V[t], u[t]] \]
\[ K u[t] \]
\[ dTdu[t] = D[U[t], u[t]] \]
\[ 0 \]
\[ EOM = ddTdvdt[t] - dTdu[t] + dVdu[t] == Q[t] \]
\[ K u[t] + M u''[t] == f[t] - C u'[t] \]
10.2 An elastic pendulum

For the elastic pendulum problem considered earlier, the first coordinate is $\theta(t)$, and is called $q(t)$ in the Maple commands and $q[t]$ in the Mathematica commands. The second coordinate is $u(t)$ called $u(t)$ in Maple and $u[t]$ in Mathematica.

10.2.1 Using Maple

> with(Physics):
> Setup(mathematicalnotation=true)

> v1 := diff(q(t),t):

\[
\frac{dv1}{dt} := \frac{d}{dt} q(t)
\]

> v2 := diff(u(t),t):

\[
\frac{dv2}{dt} := \frac{d}{dt} u(t)
\]

> T := (1/2) * M * ((l+u(t))*v1)^2 + (1/2) * M * v2^2;

\[
T := \frac{1}{2} M (l + u(t)) \frac{d}{dt} q(t) + \frac{1}{2} M \frac{d}{dt} u(t)
\]

> V := M * g * (l - (l+u(t)) * cos(q(t))) + (1/2) * K * u(t)^2;

\[
V := M g (l - (l + u(t)) \cos(q(t))) + \frac{1}{2} K u(t)^2
\]

> EOMq := diff( diff(T,v1) , t) - diff(T,q(t)) + diff(V,q(t));

\[
EOMq := 2 M (l + u(t)) \frac{d}{dt} q(t) \frac{d}{dt} u(t) + M (l + u(t)) \frac{d}{dt} q(t) + M g (l + u(t)) \sin(q(t))
\]

> EOMu := diff( diff(T,v2) , t) - diff(T,u(t)) + diff(V,u(t));

\[
EOMu := M \frac{d}{dt} u(t) - M (l + u(t)) \frac{d}{dt} q(t) - M g \cos(q(t)) + K u(t)
\]
10.2.2 Using Mathematica

\[
\text{KE} = \frac{1}{2} * M * ((1 + u[t]) * D[q[t], t])^2 + \frac{1}{2} * M * D[u[t], t]^2 \\
\left(\frac{1}{2}\right) M (1 + u[t])^2 q'[t]^2 + \left(\frac{1}{2}\right) M u'[t]^2
\]

\[
\text{PE} = M * g * (1 - (1 + u[t]) * \cos[q[t]]) + \frac{1}{2} * K * u[t]^2 \\
\left(\frac{1}{2}\right) K u[t]^2 + g M (1 - \cos[q[t]] (1 + u[t]))
\]

\[
\text{Collect[EOMq} = \text{D[D[KE, D[q[t], t]], t]} + \text{D[PE - KE, q[t]], \{q''[t], q'[t], q[t]\}} \\
\text{g M \sin[q[t]] (1 + u[t]) + 2 M (1 + u[t]) \cdot q'[t] \cdot u'[t] + M (1 + u[t])^2 q''[t]}
\]

\[
\text{Collect[EOMu} = \text{D[D[KE, D[u[t], t]], t]} + \text{D[PE - KE, u[t]], \{u''[t], u'[t], u[t]\}} \\
\text{-g M \cos[q[t]] - 1 M q'[t]^2 + u[t] (K - M q'[t]^2) + M u''[t]}
\]

The Maple and Mathematica expressions EOMq and EOMu are the same equations of motion as the previously-derived equations (40) and (41).
11 Matlab simulation of an elastic pendulum

To simulate the dynamic response of a system described by a set of ordinary differential equations, the system equations may be written in a state variable form, in which the highest-order derivatives of each equation ($\ddot{\theta}$ and $\ddot{u}$ in this example) are written in terms of the lower-order derivatives ($\dot{\theta}$, $\dot{u}$, $\theta$, and $u$ in this example). The set of lower-order derivatives is called the state vector. In this example, the equations of motion are re-expressed as

$$\ddot{\theta} = -\frac{(2\dot{u}\dot{\theta} + g\sin\theta)}{(l + u)}$$  \hspace{1cm} (44)

$$\ddot{u} = (l + u)\dot{\theta}^2 - \frac{(K/M)u + g\cos\theta}{(l + u)}$$  \hspace{1cm} (45)

In general, the state derivative $\dot{x} = \begin{bmatrix} \dot{\theta}, \dot{u}, \ddot{\theta}, \ddot{u} \end{bmatrix}^T$ is written as a function of the state, $x = \begin{bmatrix} \theta, u, \dot{\theta}, \dot{u} \end{bmatrix}^T$, $\dot{x}(t) = f(t, x)$. The equations of motion are written in this way in the following MATLAB simulation.

```matlab
% elastic_pendulum_sim

% --------------------------------------------------------------- elastic\_pendulum\_sys

\text{END}
Free response of an elastic pendulum from an initial rotational velocity, \( \dot{\theta}(0) \) of 0.5 rad/s for \( l = 1.0 \) m, \( g = 9.8 \) m/s\(^2\), \( K = 25.6 \) N/m, and \( M = 1 \) kg. \( T_k = 2\pi\sqrt{M/K} = 1.242 \) s. \( T_l = 2\pi\sqrt{l/g} = 2.007 \) s. Even though \( T_k/T_l \approx (\sqrt{5} - 1)/2 \), the least rational number, the record repeats every 24 seconds. Note that in the absence of internal damping and external forcing, the sum of kinetic energy and potential energy is constant. Why is it that the internal potential energy becomes negative as compared to it’s initial value? What is the initial configuration of the system \((\theta(0), u(0))\) in this example? About what values do \( \theta(t) \) and \( u(t) \) oscillate for \( t > 0 \)? (spyrograph!) An animation of this motion is here: http://www.duke.edu/~hpgavin/cee541/elastic_pendulum_sim.mp4
12 Constraints

Suppose that in a dynamical system described by $m$ generalized dynamic coordinates,

$$q(t) = [q_1(t), q_2(t), \cdots, q_m(t)]$$

the coordinate trajectories must satisfy additional (constraining) relationships $g(q) = 0$. For example, suppose the elastic pendulum must move along a particular line, $g(\theta(t), u(t)) = 0$, or that the pendulum can not move past a particular line, $g(\theta(t), u(t)) \leq 0$. If these constraints to the motion of the system can be written purely in terms of the positions of the coordinates, then the system (including the differential equations and the constraints) is called a holonomic system.

There are a number of intriguing terms connected to constrained dynamical systems.

- A system with constraints that depend only on the position of the coordinates,

$$g(q(t), t) = 0$$

is holonomic.

- A system with constraints that depend on the position and velocity of the coordinates,

$$g(q(t), \dot{q}(t), t) = 0$$

(in which $g(q(t), \dot{q}(t), t)$ can not be integrated into a holonomic form) is nonholonomic.

- A system with constraints that are independent of time,

$$g(q) = 0 \quad \text{or} \quad g(q, \dot{q}) = 0$$

is scleronomic.

- A system with constraints that are explicitly dependent on time, as in the constraints listed under the first two definitions is rheonomic.

- A system with constraints that are linear in the velocities,

$$g(q(t), \dot{q}(t)) = f(q(t)) \cdot \dot{q}(t)$$

is pfafian.

Any unconstrained system must be forced to adhere to a prescribed constraint. The required constraint forces $Q^C$ are collocated with the generalized coordinates $q$, and the virtual work of the constraint forces acting through virtual displacements is zero\(^5\)

$$Q^C \cdot \delta q = 0.$$

Geometrically, the constraint forces are normal to the displacement variations.

12.1 Holonomic systems

Consider a constraint for the elastic pendulum in which the pendulum must move along a curve \( g(\theta(t), u(t)) = 0 \). For example, consider the constraint

\[
u(t) = l - l\theta^2(t) \iff g(\theta(t), u(t)) = 1 - \theta^2(t) - u(t)/l .\]

Clearly the elastic pendulum will not follow the path \( g = 0 \) all by itself; it needs to be forced, somehow, to follow the prescribed trajectory. In a holonomic system (in which the constraints are on the coordinate positions) it can be helpful to think of a frictionless guide that enforces the dynamics to evolve along a particular line, \( g(q) = 0 \). The guide exerts constraint forces \( Q^C \) in a direction transverse to the guide, but not along the guide.

For relatively simple systems such as this, incorporating a constraint can be as simple as solving the constraint equation for one of the coordinates, for example, \( u(t) = l - l\theta^2(t) \) and substituting that expression into the Lagrangian or the unconstrained equations of motion. With the substitution of \( u(t) = l - l\theta^2(t) \) into the expressions for kinetic energy and potential energy, Lagrange's equations can be written in terms of the remaining coordinate, \( \theta \). This is a perfectly acceptable means of incorporating holonomic constraints into an analysis. However, in general, a set of \( c \) constraint equations \( g(q) = 0 \) need not be re-arranged to express the position of \( c \) coordinates in terms of the remaining \( (m - c) \) coordinates. Furthermore, reducing the dimension of the system by using the constraint equation to eliminate variables does not give us the forces required to enforce the constraints, and therefore misses an important aspect of the behavior of the system. So a more general approach can be followed in order to derive the equations of motion for constrained systems.

Recall that an admissible variation, \( \delta q \), must adhere to all constraints. For example, the solution to the constrained elastic pendulum, perturbed by \( [\delta \theta, \delta u] \), must lie along the curve \( 1 - \theta^2 - u/l = 0 \). In order for the variation \( \delta q \) to be admissible, the perturbed solution must also lie on the line of the constraint. A constraint evaluated at a perturbed solution \( q + \delta q \), in general, can be approximated via a truncated Taylor series

\[
g(q + \delta q, t) = g(q, t) + \left[ \frac{\partial g}{\partial q} \right] \delta q + \text{h.o.t.} .
\]

The constraints at the perturbed solution are satisfied for infinitesimal perturbations as long as the variation \( \delta q \) is orthogonal to the gradient of \( g \) with respect to \( q \),

\[
\left[ \frac{\partial g}{\partial q} \right] \delta q = 0 .
\]

Because admissible variations \( \delta q \) are normal to \( [\partial g/\partial q] \) and the constraint force \( Q^C \) is normal to \( \delta q \), the constraint force must lie within the subspace spanned by \( [\partial g/\partial q] \),

\[
Q^C = \lambda^T \left[ \frac{\partial g}{\partial q} \right] .
\]
The constraint forces $Q^C_j$ may now be added into Lagrange’s equations as the forces required to adhere the motion to the constraints $g_i(q) = 0$.

\[
\frac{d}{dt} \left( \frac{\partial T}{\partial \dot{q}_j} \right) - \frac{\partial T}{\partial q_j} + \frac{\partial V}{\partial q_j} - \sum_i \lambda_i \frac{\partial g_i}{\partial q_j} - Q_j = 0
\]

in which

\[
\sum_i \lambda_i \frac{\partial g_i}{\partial q_j}
\]

is the generalized force on coordinate $q_j$ applied through the system of constraints,

\[
g(q, t) = 0.
\]

These forces are precisely the actions that enforce the constraints. Equations (47) and (48) uniquely describe the dynamics of the system. In numerical simulations these two systems of equations are solved simultaneously for the accelerations, $\ddot{q}(t)$, and the Lagrange multipliers, $\lambda(t)$, from which the constraint forces, $Q^C(t)$, can be found.

A system with $m$ coordinates and $c$ holonomic constraints can be reduced to a system of $m - c$ equations of motion by substituting constraint equations into the equations of motion and eliminating coordinates. Alternatively, the Lagrange multipliers can be treated as dynamic variables, and the constraint equations can be enforced in the acceleration form, by differentiating them twice with respect to time. In either case, the initial conditions must be admissible, and numerical integration errors that would lead to dynamic responses that violate $g(q, t) = 0$ must be numerically corrected.
Let’s apply this to the elastic pendulum, constrained to move along a path

\[ u(t) = l - l\theta^2(t) \quad \iff \quad g(\theta(t), u(t)) = 1 - \theta^2(t) - u(t)/l . \]  

(49)

The derivatives of \( T \) and \( V \) are as they were. The new derivatives required to model the actions of the constraints are

\[
\frac{\partial g}{\partial q_1} = \frac{\partial g}{\partial \theta} = -2\theta \tag{50}
\]

\[
\frac{\partial g}{\partial q_2} = \frac{\partial g}{\partial u} = -1/l \tag{51}
\]

Note that these derivatives are related to, but are not the same as, the gradient of \( g(q) \). Equation (40) now includes a new term for the constraint moment in the \( \theta \) direction, \( +\lambda(2\theta) \), and the new term for the constraint force in the \( u \) direction in equation (41) is \( +\lambda(1/l) \). (This problem has one constraint, and therefore one Lagrange multiplier, but two coordinates, and therefore two generalized constraint forces.) The Lagrange multiplier in this problem has units of \textit{moment} (N.m). There are no other non-conservative forces \( Q_j \) applied to this system.

The problem now involves three equations (two equations of motion and the constraint) and three unknowns \( \theta, u \) (or their derivatives) and \( \lambda \). In principle, a solution can be found. In solving the equations of motion numerically, as a system of first-order o.d.e’s, we solve for the highest order derivatives in each equation in terms of the lower-order derivatives. In this case the highest order derivatives are \( \ddot{\theta} \) and \( \ddot{u} \). In the case of constrained dynamics, we also need to solve for the Lagrange multiplier(s), \( \lambda \). The constraint equation(s) give(s) the additional equation(s) to do so. But in this problem the constraint equation is in terms of positions \( \theta \) and \( u \). However, by differentiating the constraint we can put this in terms of accelerations \( \ddot{\theta} \) and \( \ddot{u} \). So doing, with some rearrangement,

\[ 2l\theta\ddot{\theta} + \ddot{u} = -2l\dot{\theta}^2 . \]  

(52)

Now we have three equations and three unknowns for \( \ddot{\theta}, \ddot{u}, \) and \( \lambda \).

\[
M(l + u)^2\ddot{\theta} + 2\theta\lambda = -Mg(l + u)\sin\theta - 2M(l + u)\dot{u}\dot{\theta} \tag{53}
\]

\[
M\ddot{u} + \frac{1}{l}\lambda = M(l + u)\dot{\theta}^2 - Ku + Mg\cos\theta \tag{54}
\]

\[
2l\theta\ddot{\theta} + \ddot{u} = -2l\dot{\theta}^2 \tag{55}
\]

The constraint \textit{moment} in the \( \theta \) direction is \( \lambda(2\theta) \) and the constraint \textit{force} in the \( u \) direction is \( \lambda/l \). The constraint forces acting along \( g(q) = 0 \) are \( \lambda/l \) in the \( u \) direction and \( 2\theta\lambda/(l + u) \) perpendicular to the \( u \) direction. The three equations may be written in matrix form . . .

\[
\begin{bmatrix}
M(l + u)^2 & 0 & 2\theta \\
0 & M & 1/l \\
2\theta & 1/l & 0
\end{bmatrix}
\begin{bmatrix}
\ddot{\theta} \\
\ddot{u} \\
\lambda
\end{bmatrix}
= \begin{bmatrix}
-Mg(l + u)\sin\theta - 2M(l + u)\dot{u}\dot{\theta} \\
M(l + u)\dot{\theta}^2 - Ku + Mg\cos\theta \\
-2\dot{\theta}^2
\end{bmatrix} \tag{56}
\]

Note that the initial condition of the system must also adhere to the constraints,

\[
l\theta_0^2 + u_0 = l \tag{57}
\]

\[
2l\theta_0\dot{\theta}_0 + \dot{u}_0 = 0 \tag{58}
\]
These equations can be integrated numerically as was shown in the previous MATLAB example, except for the fact that in the presence of constraints, the accelerations and Lagrange multiplier need to be evaluated as a solution of three equations with three unknowns.
Figure 3. Free response of an undamped elastic pendulum from an initial condition \( u_0 = l \) and \( \dot{\theta}_o = 1 \) constrained to move along the arc \( u = l - l\theta^2 \). The motion is periodic and the total energy is conserved exactly.

Figure 4. The constrained motion of the pendulum is seen to satisfy the equation \( u = l - l\theta^2 \) for \( l = 1 \) m. An animation of this motion and the dynamic constraint forces is here: http://www.duke.edu/~hpgavin/cee541/elastic_pendulum_H_sim.mp4

Figure 5. The constraint moment in the \( \theta \) direction (blue) and force in the \( u \) direction (green) required to enforce the constraint \( u(t) = l - l\theta^2(t) \).
12.2 Nonholonomic systems

A nonholonomic system has internal constraint forces \( Q^C_j \) which adhere to a non-integrable relationship involving the positions and velocities of the coordinates,

\[
g(q, \dot{q}, t) = 0 .
\]

The constraint forces \( Q^C_j \) are normal to the constraint surface \( g(q, \dot{q}, t) = 0 \). As always, any admissible variations must satisfy the constraints

\[
g(q + \delta q, \dot{q} + \delta \dot{q}, t) = g(q, \dot{q}, t) + \left[ \frac{\partial g}{\partial q} \right] \delta q + \left[ \frac{\partial g}{\partial \dot{q}} \right] \delta \dot{q} + \text{h.o.t.} = 0
\]

So, for infinitesimal variations,

\[
\left[ \frac{\partial g}{\partial q}, \frac{\partial g}{\partial \dot{q}} \right] \cdot \left[ \delta q, \delta \dot{q} \right] = 0 .
\]

It may be shown\(^6\) that this condition is equivalent to

\[
\left[ \frac{\partial g}{\partial \dot{q}} \right] \cdot \delta q = 0 \quad (60)
\]

which is the constraint on the displacement variations for nonholonomic systems.

Since admissible variations \( \delta q \) are normal to \( [\partial g/\partial \dot{q}] \), the constraint forces must therefore lie within \( [\partial g/\partial \dot{q}] \),

\[
Q^C = \lambda^T \left[ \frac{\partial g(q, \dot{q})}{\partial \dot{q}} \right] .
\]

Including these constraint forces into Lagrange’s equations gives the nonholonomic form of Lagrange’s equations\(^7,^8\)

\[
\frac{d}{dt} \left( \frac{\partial T}{\partial \dot{q}_j} \right) - \frac{\partial T}{\partial q_j} + \frac{\partial V}{\partial q_j} - \sum_i \lambda_i \frac{\partial g_i}{\partial \dot{q}_j} - Q_j = 0 ,
\]

in which

\[
\sum_i \lambda_i \frac{\partial g_i}{\partial \dot{q}_j}
\]

is the generalized force on coordinate \( q_j \) applied through the system of constraints \( g = 0 \). Equations (59) and (61) uniquely prescribe the constraint forces (Lagrange multipliers \( \lambda \)) and the dynamics of a system constrained by a function of velocity and displacement.

\(^8\)M.R. Flannery, “d’Alembert-Lagrange analytical dynamics for nonholonomic systems,” *J. Mathematical Physics* 52 032705 (2011)
As an example, suppose the dynamics of the elastic pendulum are controlled by some internal forces so that the direction of motion \( \arctan(dy/dx) \) is actively steered to an angle \( \phi \) that is proportional to the stretch in the spring, \( \phi = -bu/l \). The velocity transverse to the steered angle must be zero, giving the constraint,

\[
\frac{\dot{u}}{\dot{\theta}} = \tan(\theta + bu/l) \quad \iff \quad g(\theta, u, \dot{\theta}, \ddot{u}) = \dot{u} \cos(\theta + bu/l) - l\dot{\theta} \sin(\theta + bu/l)
\]  

(62)

The additional derivatives required for the nonholonomic form of Lagrange’s equations are

\[
\frac{\partial g}{\partial \dot{q}_1} = \frac{\partial g}{\partial \theta} = -l \sin(\theta + bu/l) 
\]

(63)

\[
\frac{\partial g}{\partial \dot{q}_2} = \frac{\partial g}{\partial u} = \cos(\theta + bu/l)
\]

(64)

Equation (40) now includes a new term for the constraint moment in the \( \theta \) direction, \(-\lambda(ls)\), and the new term for the constraint force in the \( u \) direction in equation (41) is \(+\lambda(c)\), where \( s = \sin(\theta + bu/l) \) and \( c = \cos(\theta + bu/l) \). Note that in this case, the constraint forces are dependent upon the position of the pendulum (\( \theta \) and \( u \)), but not on the velocities. The constraint equation along with the equations of motion uniquely define the solution \( \theta(t), u(t), \) and \( \lambda(t) \). Since, for numerical simulation purposes, we are interested in solving for the accelerations, \( \ddot{\theta}(t) \) and \( \ddot{u}(t) \), we can differentiate the constraint equation to transform it into a form that is linear in the accelerations,

\[
\dot{g} = -bu^2s/l + \ddot{u}c - l\dot{\theta}^2c - l\dot{\theta}s - \dot{\theta}\dot{u}(s + bc)
\]

(65)

Our three equations are now,

\[
M(l + u)^2\ddot{\theta} - (ls)\lambda = -Mg(l + u)\sin\theta - 2M(l + u)\dot{\theta}\dot{\theta}
\]

(66)

\[
M\ddot{u} + (c)\lambda = M(l + u)\dot{\theta}^2 - Ku + Mg\cos\theta
\]

(67)

\[
-(ls)\ddot{\theta} + (c)\ddot{u} = l\dot{\theta}^2c + \dot{\theta}\dot{u}(s + bc) + bu^2s/l
\]

(68)

with an initial condition that also satisfies the constraint, \( \dot{u}_0 = l\dot{\theta}_0 \tan(\theta + bu/l) \). The three equations may be written in matrix form . . .

\[
\begin{bmatrix}
M(l + u)^2 & 0 & -ls \\
0 & M & c \\
-ls & c & 0
\end{bmatrix}
\begin{bmatrix}
\ddot{\theta} \\
\ddot{u} \\
\lambda
\end{bmatrix} =
\begin{bmatrix}
-Mg(l + u)\sin\theta - 2M(l + u)\dot{\theta}\dot{\theta} \\
M(l + u)\dot{\theta}^2 - Ku + Mg\cos\theta \\
l\dot{\theta}^2c + \dot{\theta}\dot{u}(s + bc) + bu^2s/l
\end{bmatrix}
\]

(69)

Note that the upper-left 2 \( \times \) 2 blocks in the matrices of equations (56) and (69) are the same as the corresponding matrix \( M \) in the unconstrained system (42). The same is true for the first two elements of the right-hand-side vectors of equations (56) and (69) and the right-hand-side vector \( Q \) of the unconstrained system (42). Furthermore, if the differentiated constraint equations (52) and (65) are written as

\[
\dot{g} = A(q(t), \dot{q}(t)) \ddot{q}(t) - b(q(t), \dot{q}(t), t)
\]

then both equations (56) and (69) may be written

\[
\begin{bmatrix}
M & A^T \\
A & 0
\end{bmatrix}
\begin{bmatrix}
\ddot{q} \\
\lambda
\end{bmatrix} =
\begin{bmatrix}
Q \\
b
\end{bmatrix}.
\]

(70)

This expression can be obtained directly from Gaun’s principle of least constraint, which provides an appealing interpretation of constrained dynamical systems.
Figure 6. Free response of an undamped elastic pendulum from an initial condition $u_0 = l/2$, $\theta_0 = 0.2$ rad, $\dot{\theta}_0 = 1$ rad/s, with trajectory constrained by $l\dot{\theta}/\dot{u} = \tan(\theta + bu/l)$, with $b = 5$. The motion is not periodic but total energy is conserved exactly and the constraint is satisfied at all times.

Figure 7. The constrained motion of the pendulum does not follow a fixed relation between $u$ and $\theta$ — the constraint is nonholonomic. An animation of this motion and the dynamic constraint forces is here: http://www.duke.edu/~hpgavin/cee541/elastic_pendulum_NH_sim.mp4 (ying & yang)

Figure 8. The constraint moment in the $\theta$ direction (blue) and the force $u$ direction (green) directions required to enforce the constraint $l\dot{\theta}/\dot{u} = \tan(\theta + bu/l)$. 

BY-NC-ND
HP Gavin August 19, 2020
13 Gauss’s Principle of Least Constraint

Consider the equations of motion of the unconstrained system written as equation (43),

\[ M(q,t) \ddot{a} = Q(q, \dot{q}, t) . \]

The matrix \( M \) is assumed to be symmetric and positive definite. Define the accelerations of the unconstrained system as

\[ a \equiv M^{-1}Q \]

and write the differentiated constraints in terms of the constrained accelerations \( \ddot{q} \) as

\[ A(q, \dot{q}, t) \ddot{q} = b(q, \dot{q}, t). \]

The constrained system requires additional actions \( Q^C \) to enforce the constraint, so the equations of motion of the constrained system are

\[ M(q,t) \ddot{q} = Q(q, \dot{q}, t) + Q^C(q, \dot{q}, t) . \]

Lastly, define a quadratic form of the accelerations,

\[ G = \frac{1}{2} (\ddot{q} - a)^T M (\ddot{q} - a) \]

Gauss’s Principle of Least Constraint\(^9\)\(^10\) states that the accelerations of the constrained system \( \ddot{q} \) minimize \( G \) subject to the constraints \( A\ddot{q} = b \). The naturally-constrained accelerations \( \ddot{q} \) are as close as possible to the unconstrained accelerations \( a \) in a least-squares sense and at each instant in time while satisfying the constraint \( A\ddot{q} = b \).

To minimize a quadratic objective subject to a linear constraint the objective can be augmented via Lagrange multipliers \( \lambda \),

\[ G_A = \frac{1}{2} (\ddot{q} - a)^T M (\ddot{q} - a) + \lambda^T (A \ddot{q} - b) \]

\[ = \frac{1}{2} \ddot{q}^T M \ddot{q} + \ddot{q}^T Ma + \frac{1}{2} a^T Ma + \lambda^T A\ddot{q} - \lambda^T b \]

minimized with respect to \( \ddot{q} \),

\[ \left( \frac{\partial G_A}{\partial \ddot{q}} \right)^T = 0 \iff M\ddot{q} = Q - A^T \lambda \]

(72)

and maximized with respect to \( \lambda \),

\[ \left( \frac{\partial G_A}{\partial \lambda} \right)^T = 0 \iff A\ddot{q} = b \]

(73)

These conditions are met in equation (70), as derived earlier for both holonomic and non-holonomic systems,

\[ \begin{bmatrix} M & A^T \\ A & 0 \end{bmatrix} \begin{bmatrix} \ddot{q} \\ \lambda \end{bmatrix} = \begin{bmatrix} Q \\ b \end{bmatrix} . \]

The force of the constraints is now apparent, $Q^C = -A^T \lambda$. While equation (70) is sufficient for analyzing the behavior and simulating the response of constrained dynamical systems, it is also useful in building an understanding of their nature. Solving the first of the equations for $\ddot{q}$,

$$\ddot{q} = M^{-1}Q - M^{-1}A^T \lambda$$

and inserting this expression into the constraint equation,

$$AM^{-1}Q - AM^{-1}A^T \lambda = b$$

the Lagrange multipliers may be found,

$$\lambda = -(AM^{-1}A^T)^{-1}(b - AM^{-1}Q)$$

and substituting $a = M^{-1}Q$, the constraint force, $Q^C = -A^T \lambda$, can be found as well,

$$Q^C = -A^T(AM^{-1}A^T)^{-1}(Aa - b).$$

or

$$Q^C = K(Aa - b).$$

The difference $(Aa - b)$ is the amount of the constraint violation associated with the unconstrained accelerations $a$. If the unconstrained accelerations satisfy the constraint, then the constraint force is zero. The matrix $K = -A^T(AM^{-1}A^T)^{-1}$ is a kind of natural nonlinear feedback gain matrix that relates the constraint violation of the unconstrained accelerations $(Aa - b)$ to the constraint force required to bring the constraint to zero, $Q^C$.

The constrained minimum of the quadratic objective $G$ gives the correct equations of motion.
